A COMPARATIVE STUDY OF ARGOECOLOGICAL LAND USE PATTERNS USING GIS
BETWEEN THE EARLY AGRICULTURAL SOCIETIES OF
THE MONONGAHELA & THE ONEOTA

Jenica M. Simon, B.S.

University of Wisconsin-La Crosse, 2010

ABSTRACT

This project is a multidisciplinary study between Archaeology and Geographic Information Systems (GIS). Looking at the transition from hunters and gathers to agricultural subsistence and how this is reflected in the settlement patterns with the positive association of suitable agricultural soils. Furthering research begun in 2009 by Anderson & Simon, this project compares the highly maize dependent Monongahela to the maize horticultural practices of the Oneota. The Monongahela upland pattern can be linked to more productive maize agricultural soils proving suggesting an increase in agriculture not warfare shifted the settlement pattern. Furthermore, the archaeological record demonstrates the transition in settlement patterns as non-agricultural Archaic and Woodland have been demonstrated to have quantifiably lower soil correlations than agricultural time periods, peaking in the Middle Monongahela. On the other hand, Oneota localities show two different patterns. The Middle Fox River Passageway reflect the middle of the spectrum with the patterns leaning towards agricultural land use, while the La Crosse Terrace shows little preference for agriculturally suited soil suggesting that other subsistence resources remained more important or pointing to an explanation of intensive ridge field systems. This dichotomy in Oneota localities is evidence arguing for the separation of the La Crosse Terrace Region from other Oneota localities throughout Wisconsin.

ACKNOWLEDGEMENTS

A special thanks to my readers,

Dr. David A. Anderson
Dr. Constance Arzigian
Dr. James Theler

And special thanks to my peer reading group,
Michael Lager
Megan Leigl
Michael McQuinn
Sheila Oberreuter

And again special thanks to these individuals,
Seth A. Schneider, University of Wisconsin- Milwaukee

Another special thanks to my family and friends for making this research possible.

INTRODUCTION

The prehistoric shift from hunters and gatherers to agricultural societies represents a larger cultural change than the entirety of written history combined. This agricultural revolution was so successful it left only a few hunting and gathering cultures to survive with none surviving untouched today. Despite the importance of this transition little can be said for certain, and many researchers simply use the appearance of agriculture in the determination of the next cultural periods rather than focusing on the transition itself, while paleoethnobotanists rarely relate numerical data spatially and temporally back to the culture and the change in subsistence they can represent. Current research has begun to reflect on past investigations to validate or disprove previously made claims about subsistence in relations to land use patterns and provide evaluation with new computer technologies.

Research begun in 2009 by Anderson & Simon focused on the land use debates demonstrated by Johnson et al. (1989) of the curious upland settlement pattern demonstrated by the Monongahela; furthermore, discussions of Gallagher et al. (1985) of Oneota seasonal settlement patterns lead to this comparison of two early maize agricultural societies. The emergence of maize agriculture at any level, be it full scale or small garden beds, is reflected in a shift in land use as people must become sedentary, at least for the growing season, and often seek out the best natural soils to grow their crops, and this land use pattern grows with the culture's reliance on maize. The Monongahela Culture occupied the Upper Ohio River Valley from A.D. 1100 to A.D. 1630., The site distribution data demonstrates their land use pattern shifting to upland areas for the advantage of superior crop land rather than military security during the

Middle Monongahela phase; meanwhile, the Oneota Culture settled much of the Upper Midwest from A.D. 923 to A.D. 1720 and still seasonally moved around for other resources. They had substantial facilities investments-hundreds of acres of ridged fields, thousands of deep storage pits and were very different from the Late Woodland horticulturalists, even if they are not on the scale of the Monongahela villages. Bone isotope analysis depicts a rising reliance on maize agriculture for the Ohio Valley from -7.64 to -21.89 $\delta^{13}\text{C}$ in over 426 specimens over twenty-five sites reported by Greenlee (2002), while Pratt (1994) reports that the Upper Mississippi River in Wisconsin reliance is around -13.1 to -22.3 $\delta^{13}\text{C}$ in from a significantly smaller skeleton assemblage of twenty-three throughout three sites.

Using methods of spatial analysis available through modern Geographic Information System (GIS) technology it is possible to reevaluate proposed explanations for settlement shifts by examining ecologically based datasets. Examining the correlations between site location and prime agricultural soil directly surrounding known sites will yield positive results for shifting land use patterns as time progresses and the society becomes more dependent on agriculture. Research with the Monongahela Culture demonstrated that agriculturally productive soils were actually more abundant in upland locations, yet the Oneota Culture results depict a relatively low correlation with maize producing soils, they were still significantly different than non-agricultural Archaic and Woodland settlement patterns previously investigated in the Monongahela study (Anderson and Simon2009b).

BACKGROUND

This project is a multidisciplinary look at the archaeology of early agriculture societies and their land use patterns regionally using GIS techniques. So a general overview of North American

origins of agriculture will lead into a review of early agricultural societies; focusing specifically on the Monongahela and Oneota, describing the ecological regions they occupied concluded by a brief review of the history of GIS & Archaeology.

Origins of Agriculture in North America

Subsistence patterns are the way a culture, society, or a group of people provide the necessary means of survival usually referring to foodstuffs. Unfortunately economical change, as it is sometime called, seems to present a veritable “which came first, the chicken or the egg argument” with political organization (see Table 1). Foraging is paired with band level societies and tribal and chiefdom level societies seem tied to horticulture, pastoralism, and agriculture. While this model is still employed today, it is recognized that more cultures, especially within North America, fall somewhere between these categories rather than within them. The transition between foraging, or hunting and gathering, and numerous forms of agriculture vary throughout the world. In some populations like those of the Fertile Crescent the transition was abrupt and complete, while native cultures of North America practice horticulture along with foraging strategies for hundreds of year ultimately only interrupted by the arrival of Europeans. (Smith 1998).

Table 1: Depicts the approximate date the correlating political and economic organization are present in the archaeological record.

Date	300,000 ya	12,000 ya	10,000 ya	Present
Political Organization	Band Level	Tribe/ Chiefdom	State	Global
Economic Organization (Subsistence Pattern)	Foraging/ Hunting & Gathering	Horticulture / Pastoralism	Agriculture/ Intensive Agriculture	Industrial/ Post Industrial

The origins of agriculture have been traced back by paleoethnobotanists and archaeologists and it is generally understood that there are seven centers of domestication in the ancient world. In the old world, 9,500 B.P. the Fertile Crescent, Yangtze River in the South of China around 8,500 B.P., the Yellow River in the North of China around 9,500 B.P., and much later in Sub-Saharan Africa as portrayed in Figure 1. In the Western hemisphere, agriculture emerged around 9,000 B.P. in Central Mexico, developing the famous New World triad, a dietary complete combination of maize, squash, and beans. In South America in the southern reaches of the Andes at approximately 7,000 B.P. native peoples domesticate an abundance of crops including potatoes, cotton, chili peppers, manioc, and sweet potatoes. Much later around 5,500 B.P. in the Eastern United States, native inhabitants domesticated sumpweed and sunflowers for protein and oils and various species of chenopod as source of grain. (Cowan & Watson 1992).

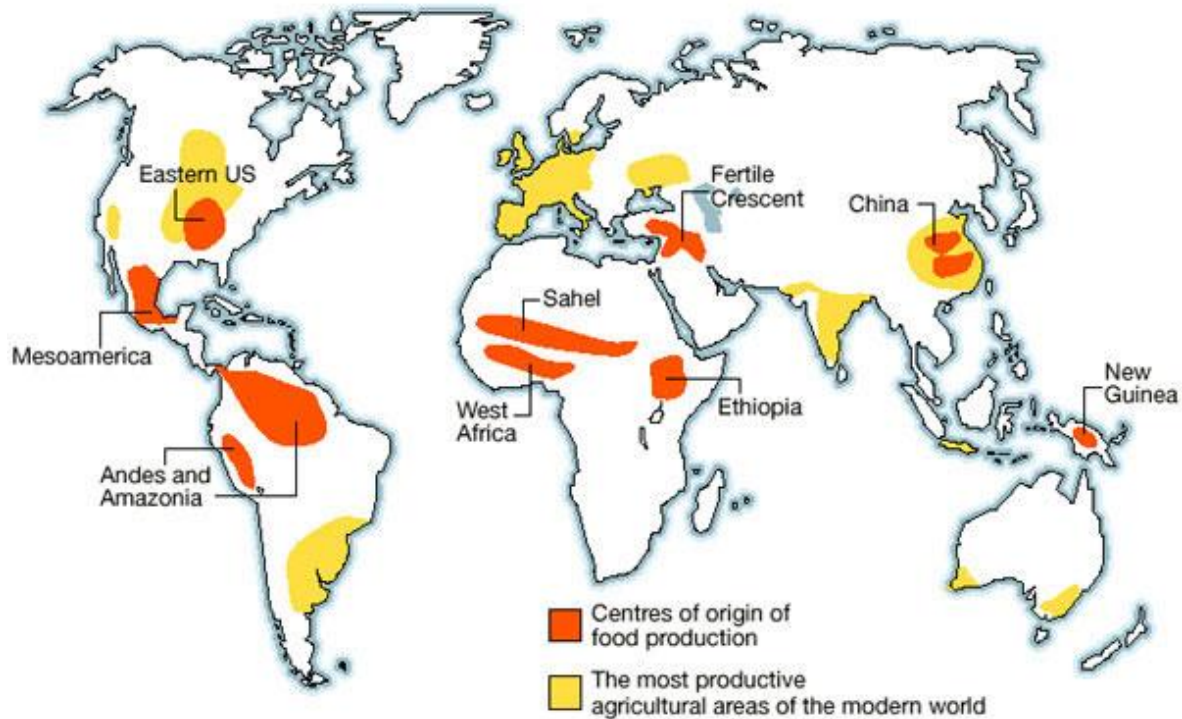

Figure 1: Archaeological centers of domestication versus current agricultural land use pattern around the world. (Source: Diamond 2002).

North American agriculture owes a great deal to the development of the triad in Mesoamerica. Maize was the dominant agricultural crop of North America despite the widespread domestication of several local domesticates of chenopodium and other grass-like varieties. Smith (1998) states that around 1200 B.C. maize was introduced to the Southwestern United States and it took roughly a thousand years to reach the Eastern Woodlands via the Great Plains. But a culture's reliance on maize often changed throughout time and not always towards a greater dependency either.

Early Agricultural Societies

By late prehistory a variety of maize adapted cultures had arisen across the North American landscape. Very few prehistoric maize agriculturalists depended solely on farming resembling

our post-industrial society, but rather most often supplemented protein from terrestrial and aquatic animals as well as other essential nutrients from other wild, seasonal resources. The most well documented maize agriculturalist were in the Eastern portion of the United States and included the Monongahela, Susquehannock, Huron, Seneca, Oneida, and Mohawk. Early European settlers documented many native tribes spent their summers tending to the corn fields, their falls harvesting, and survived off their stores during the winter. Further to the west, Mississippian and Oneota with many others cultures within the Great Plains and Southwest regions brought maize into their subsistence patterns as their culture expanded.

The two cultures on which this study will focus are the late prehistoric Monongahela of southwestern Pennsylvania and the late prehistoric Oneota of Wisconsin.

Monongahela

The Monongahela culture was first discovered in 1939 through the work of Mary Butler in Somerset County, Pennsylvania conducted under the Works Progress Administration. By 1940 the research program had established community patterns based on seventeen excavated sites, giving us detailed descriptions of the circular houses and attached storage facilities associated with an intensification of maize agriculture. Anderson and Simon (2009a) demonstrates how this translates to the archaeological record as semi-oval floor plans expanding outward from the circular housing structure in a flower like design with maize remains often found in context (Figure 2). Johnson et al. compiled a synthesis of the Monongahela culture in 1989 and it is this work forms the basis for the following summary.

The Monongahela culture is typically be divided into four cultural periods with several geographically based phases in each (Figure 3). They are the Early Monongahela circa A.D. 1100-1250, the Middle Monongahela circa A.D. 1250-1580, the Late Monongahela circa A.D. 1580-1630, and the Protohistoric Monongahela circa A.D. 1630-1635.

Figure 2: Example of extreme additions to storage capacity typical of later Monongahela settlements. (Source: Anderson & Simon 2009a)

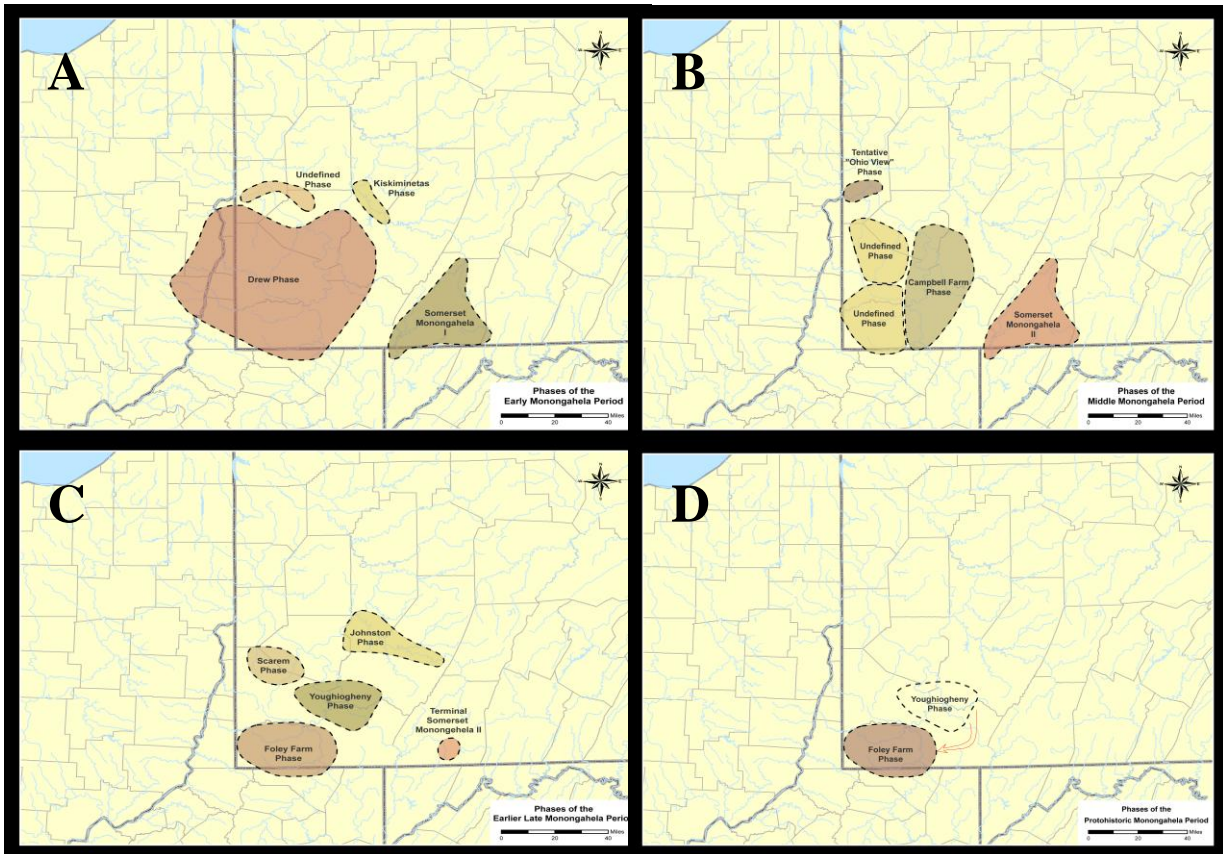

Figure 3: Spatial and temporal distribution of Monongahela Culture (A) Early Monongahela Period ca. A.D. 1100-1250; (B) Middle Monongahela ca. A.D. 1350-1580; (C) Late Monongahela ca. A.D. 1580-1630; (D) Protohistoric Monongahela ca. A.D. 1630-1635. (Source: Anderson & Simon 2009a)

The Monongahela culture occupied much of the lower portion of the Upper Ohio River Valley covering portions of modern Pennsylvania, Maryland, Western Virginia, and Ohio. The Upper Ohio River Valley area is characterized by a dendritic stream pattern creating steep sided upland locations, which has been noted as a probable environmental cause for the upland settlement pattern observed for Monongahela society. Anderson & Simon (2009a) concluded that over 70% of Monongahela sites are located on these narrow upland areas, which is atypical for agricultural societies in the Eastern United States. So the question becomes why would an agricultural society shift to those upland locations?

The Monongahela were predominately maize agriculturalists but regularly supplemented their diet with terrestrial and aquatic animals for protein. Bone isotope studies by Greenlee

(2002) show that maize was abruptly adopted and the values range from -7.64 to -21.89 $\delta^{13}\text{C}$ (Appendix A). This analysis is pretty conclusive given the fairly large sample of 426 skeletons from twenty-five sites, but bone isotope analysis is not without its flaws. Several common problems with bone isotope analysis have to do with sampling bias as many skeletons are recovered from burial context mostly of the wealthy. This only provides a snapshot into elite dietary practices, which it has been demonstrated that many elites actually gain their maize intake indirectly from animals killed while eating the unharvested maize, while low values may suggest a disease or personal, dietary preference to avoid maize (Pratt 1994).

Several theories exist to explain the Monongahela upland argument as cited in Johnson et al. 1989. William Mayer-Oakes (1955) was the first to suggest that the Monongahela upland locations were defensive positions. Later, Richard George (1974) theorized that upland locations correlated with a “militarization” of the Monongahela as large palisades became more common throughout the archaeological record, which corresponded with the continued growth of prehistoric populations in the early-middle Monongahela period. Eventually, the population pressure pushed weaker population to less agricultural successful upland locations. This theory was very popular and it was not until 1989 when William Johnson (Johnson et al.) suggested that the upland transition could be associated with greater agricultural potential linked to better agricultural productive, upland soils. Anderson & Simon (2009b) set out to test this hypothesis using a GIS analysis of modern agricultural soils and the distribution of Monongahela culture sites, along with using viewsheds to disprove any potential military advantage. The results of this study showed that of the sites located in upland locales, over 50 percent were located on soils with more agricultural productivity values above mean productivity (Anderson and Simon 2009b).

Oneota

The Oneota culture is a complex concept in and of itself. Overstreet's 1994 article calls on the archaeological community to come to a decision if the commonality of the shell tempered ceramic type is enough to classify these, apparently, different cultural localities underneath the umbrella of Oneota, a concept that was outlined by the Columbia Conference in 1962.

The Oneota prehistory, defined by Overstreet (1994), ranges from A.D. 923 to A.D. 1720 including the Emergent Horizon from AD 923-1150; Development Horizon from A.D. 1150-1350; Classic Horizon from A.D. 1350-1650; and the Historical Horizon from A.D. 1650-1720. However, this cultural chronological sequence only applies to the Middle Fox River Passage Way, the Door Peninsula Region, and the Lake Koshkonong Region localities located in Western Wisconsin, while the La Crosse Terrace Region is often considered an outlier because it traces its origins back to Red Wing, Minnesota. The La Crosse Terrace Region has temporal breakdown including Brice Prairie (A.D. 1300 - 1400), Pammel Creek (A.D.1400-1500), and Valley View (A.D. 1500-1650) (Boszhardt 1994). So for the purpose of this study the Oneota presence in Wisconsin will be referred to by the longest time frame define by Overstreet (1994) as A.D. 923- A.D.1720.

The Oneota occupied most of the Upper Midwest ranging from Ontario in the north, Missouri in the south, Nebraska and Kansas in the west, and Indiana and Michigan in the east. However, this study focuses on the localities of Oneota located in Wisconsin including the most well studied Middle Fox River Passageway, interesting for the urbanizing trend during the Classic Horizon. I have also decided to include the outlier, the La Crosse Terrace Region to assess the similarities of the settlement pattern. Figure 4 demonstrates the spatial pattern exhibited by Oneota localities present in Wisconsin.

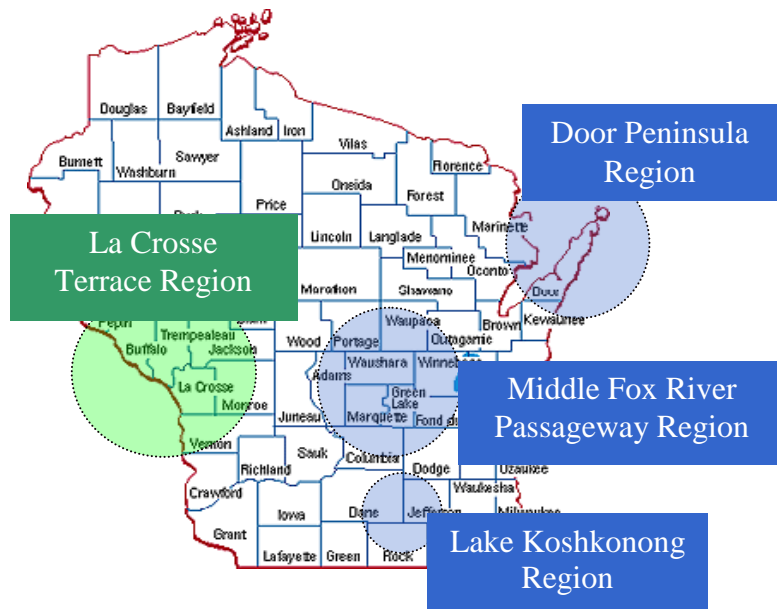

Figure 4: Oneota localities by region in Wisconsin.

The Oneota Culture are considered maize agriculturalists; in fact, if it were not obvious charred floral remains found in large storage pits and ridged fields and garden beds there would be little evidence of maize in prehistoric Wisconsin. Pratt (1994) reports that the Upper Mississippi River in Wisconsin reliance is around -13.1 to -22.3 $\delta^{13}\text{C}$ in from remains of twenty-three human skeletons throughout the three sites of Midway Village (47LC19), Overhead Site (47LC20), and Dahl Site (47LC148) all located in La Crosse County, Wisconsin. Indicating a substantial use of maize, and is very different from the Woodland values. For exact values of Pratt's bone isotope analysis see Appendix A, Table 2. While utilizing maize, the Oneota are much better known for the unusual seasonality in their subsistence strategy paired with intensive ridge agricultural systems. Many of their winter habitation sites have never been identified leading many to believe they travel to the Great Plains to hunt bison (Theler 1989). This is unusual because the ideology of agriculture usually translates directly to a sedentary lifestyle, but technically there is a short off-season from late autumn to very early spring that could be utilized

for differential resource allocation. Yet this is not to say certain groups within the Oneota did not focus on other resources while another group was devoted to growing maize. An added complexity in the La Crosse Terrace Region is that other research by Gallagher and Arzigian (1994) suggest that Oneota intensification might have revolve around diversification rather than focusing solely on maize agriculture. The harvesting wild crops may have been a major seasonal source of nutrients; for example, wild rice has been shown to represent a more significant part of the diet than previously thought perhaps more significant than the contribution made my maize agriculture.

GIS & Archaeology

Archaeology adopted GIS technology when the study of settlement patterns became prominent in the 1960s and 1970s. Since then it has evolved into two major types of study. Intra-site analysis involving correlations and calculation within a single archaeological site just as artifact density to aid in recognizing task differential areas, and inter-site analysis which is essential regional studies used in the case of predictive modeling to determine high yield survey areas where future sites might be found. With the development of stronger computer software and increasing access to subject sensitive add-ons many archaeologist now consider GIS viable methodology and many chose build their own databases to analyze traditional research questions. (Meher & Wescott 2006).

METHODOLOGY

To begin to understand how subsistence affected prehistoric settlement patterns, in this study I simplify the complex human-environmental relationship that is agriculture to the basic,

presumably positive, association between settlement location and productive agricultural soils. While GIS software is designed for spatial comparison on a magnitude of levels, I feel it is important that this correlation to be rigorously tested before compiling additional factors into the simulation. Anderson & Simon (2009b) have previously utilized a similar approach and gained positive results involving the Monongahela, a heavily maize reliant agricultural society. This project aims to test the currently developing methodology on the less reliant Oneota where seasonality not spatiality is characteristic. Results were interpreted further for comparison, and an agricultural soil productivity spectrum was developed for further studies to be evaluated in comparison to expected results.

The two cultures were selected less for representing the quantifiable highest and lowest maize reliance, but are none the less on opposite sides of the spectrum. More importantly, the spatial and tubular information about large areas of both Pennsylvania and Wisconsin had been archaeologically explored, recorded, and could be acquired.

The Monongahela of Pennsylvania actually occupied the lower portion of the Upper Ohio River Valley that spans several states. The study area was selected originally by watersheds that contained the highest density of sites but was downloaded in county format then was reformatted so the study area contained several watersheds but excluded the Somerset Monongahela because it lacks the characteristic upland settlement pattern.

Wisconsin, itself, presented a challenge as many Oneota localities exist within its borders more or less culturally independent of each other and several factors had to be considered. Overstreet (1994) suggest that the Middle Fox River Passageway represented a possible core of Oneota culture as its population grew and condensed during the Classic Horizon, while the anomaly that is the La Crosse Locality only demonstrates a slight trend towards more

upland locations from river terraces through time. These localities were the best studied and had the largest amount of sites to work with. These localities are also separated by the Tension Zone of Wisconsin, which traditionally divides arboreal ecology with conifers predominates in the North and deciduous South of the divide. But it has also been suggested the Tension Zone can be applied for agricultural conditions with lesser conditions to the North and better conditions to the South of this zone based on several factors most notably, frost-free growing days. This might be another reason for the close association with river resource, which will be discussed in some detail later. Unlike in the base experiment with Monongahela, first several counties were chosen for their abundance of Oneota cultural sites. The counties of Calumet, Fond du Lac, Green Lake, Marquette, Outagamie, Waushara, and Winnebago were selected for the Middle Fox River Passageway Region. Jackson, La Crosse, Monroe, Trempealeau, and Vernon counties were selected to represent the La Crosse Terrace Region. While the study area should not be defined by the arbitrary county lines established today it is an easy way to accumulate data in comparable and reconcilable sizes, the cut feature in ArcGIS was used to restructure the study area later.

Information (spatial and tabular) on archaeological sites was obtained digitally from the Wisconsin Historical Society and compiled using Excel database and linked to a shapefile; the processing of requests for the raw data takes time and was secured in advanced in December 2009 because the archaeological site data was needed before proceeding with rest of the project. Appendix B represents the types of data which was necessarily to conduct the agroecological model with the Oneota archaeological site dataset. Information for Site ID Number, Site Name, time period, and type of site were vital, but additional information was compiled in case it becomes useful in future research.

Information on soil types across the study areas were obtained digitally from Soil Mart (NRCS 2010). From Soil Mart, both spatial and tabular data are available providing information on the spatial extent of each soil type as well as various soil characteristics, which are proved in the Surgo Access Database. Hydrology will be far more vital than in previous studies conducted by Anderson & Simon (2009a and 2009b) because of the Oneota's proximity to and focus on wetland and aquatic resources. Hydrology tables acquired from the National Hydrography Dataset (NHD) were downloaded in the highest possible resolution available (1/3 inch) within the study area and continued to be downloading by county for consistency. Multiple 7.5-minute USGS Topographic Quadrangle maps and land cover data from the USGS seamless digital database (USGS 2009) helped in evaluating any unusual patterns caused by urban areas and archaeologists' inability to be find and excavate sites in these areas. Again with NHD data watersheds were downloaded by county and used to create more relevant boundaries for the study areas. Compiling this data and importing it into a useable format demanded a significant portion of time early in the project. Processing of collected data followed, with editing conducted in ArcGIS to correct map projection errors and standardize raw data in Microsoft Excel. Although not all the collected and confirmed datasets were analyzed during this study access to different datasets may become vial later on. A detailed metadata files were kept on how I built the database and where datasets are located for future reference (Appendix D).

To rank soil by productivity I used an attribute already present in the Surgo Database and created a query resulting in correlated data between soil type and yield of corn (bushel per acre) for non-irrigated methods. While I recognize that soil data is from contemporary soil surveys and rated productivity is measured based on using modern farming methods, including the use of modern fertilizer standards, it is also true that soil types which have characteristics that make

them good for high crop production relative to other soil types today would have also made them so in the past, no matter the agricultural technology employed. The United States Department of Agriculture actually states,

The estimate yields reflect the productive capacity of each soil for a select crop. Yields are likely to increase as new production technology is developed. The productivity of a given soil compared with that of other soils, however, is not likely to change (2009).

Thus the opposite must also be true; as a result the correlation between yield capacities will remain equivalent even if technology is decreased and will represent a general measure of soil productivity not physical bushels per acre. It should be noted that some studies actually show that small farmers that take intimate care of heavily reliant crops like maize often receive better yields than mechanized agriculture today. So following the methodology of Anderson & Simon (2009b) by reformatting the scale into standard deviation then sorting soil types by this standardized scale allows us to compare productivity without its inherit bias of bushel yields for modern agricultural practices. Archaeological sites were divided between localities, average yield in bushels was calculated based on USDA calculations, the standard deviation formula was applied, and values were rounded to the nearest 0.25 deviation for ease of comparison. See calculations and values for Oneota both localities in Appendix B.

Once the soil data was joined in tabular form to the soil shapefile the archaeological sites were spatially joined to the newly standardized soil data. The correlation became too difficult for the computer model to run considering that some archaeological records are just shovel test pits while others span several acres. To facilitate extracting the exact soil a site is located on the data was converted to a central point called a centroid calculated statistically by an application called X-tools (Data East, LLC 2009). After this process was completed the newly linked attribute table was exported to Excel to generate graphical representation of the data. Thus the sites are linked

to the established standardized productivity range observed in the local soils. Excel was used to count and calculate the cumulative percentage for different time periods. Analysis of each grouping, All, Oneota, Unknown, Oneota Village, Oneota Other, and Random, was compared using cumulative percentages of relative agricultural productivity was then be graphed into a line graph depicting the percent below and above average productivity. By following the trajectory of each line that represents a different time period change over time can be noted. This agroecological model could stand by itself but without statistically evaluation of the land use pattern by comparing it with a random sample of locations within each of the localities. Hawth's Tools (Beyer 2009) was used to generate random sites within the averaged soil productivity layer. Creating the equivalent of site locations randomly essentially adds a control to the data, producing a more comprehensive and informative look at the archaeological settlement patterns versus the natural array of soils present in the study area. The final comparison between the Monongahela agricultural settlements to the Oneota seasonality was achieved by meshing the cumulative percentage line graphs allowing the spectrum to be built in a relevant context of maize reliance.

Further statistical evaluation was conducted by performing a two variance Kolmogorov-Smirnov (K-S) Test on the results. The K-S Test assess if the difference in cumulative percentage lines is random or nonrandom by calculating for D or the distance between the cumulative percentage lines at any given value. The formula (Figure 5) is complex and impractical to calculate by hand so SPSS software was used. Each values compared were given a numeric value one or two so the software could run properly (Appendix D)

$$D_{n,n'} = \sup_x |F_{1,n}(x) - F_{2,n'}(x)|,$$

$$\sqrt{\frac{nn'}{n+n'}} D_{n,n'} > K_{\alpha'}$$

Figure 5: The Kolmogorov-Smirnov formula on the right hand side with the depiction of the significance of D value on the left. (Source: <http://www.physics.csbsju.edu/stats/KS-test.html>)

RESULTS & CONCLUSIONS

The analysis of maize agriculture reliance, relative soil productivity, and settlement patterns began with an overarching examination of the typical crop yields of corn per soil type in the Monongahela area versus those in the areas of Oneota localities. From this examination, it was evident that the productivity levels present in the study areas inhabited by the Wisconsin Oneota were much lower than those in southwestern Pennsylvania. In fact, the average number of bushels per acre for soils in Wisconsin was 101.4912 with a range of 30- 165 in the Lac Crosse Terrace Region and an average of 98.83 with a range of 30-160 in the Middle Fox River Passageway compared to Pennsylvania that had a range of 53-140 bushels per acre average to 109.6405 (Anderson and Simon 2009b).

The Monongahela study started with 1280 village sites and after corrections had 815 with properly correlating soils to compare to the Wisconsin localities of Middle Fox River

Passageway Region starting with 757 sites with 679 correlated sites and the La Crosse Terrace Region began with 2009 sites and was able to A.D. 1613. Total sites counts were used in comparison with Monongahela results so that the total numbers were comparable, but this might have created a bias because not all Wisconsin sites were settlement sites, on the contrary the ASI database often records a find of a few projectile points as a correlated site. The La Crosse Terrace Region had a breakdown of 83 Oneota, 1,530 Unknown, 71 Oneota Village, 12 Oneota Other, and 166 Random correlated sites. The Middle Fox River Valley had 86 Oneota, 593 Unknown, 56 Oneota Village, 30 Oneota Other, and 125 Random correlated sites.

Cumulative percentage graphs are an idea way to display multivariate information for multiple time periods. I chose a 0.5 standard deviation scale from -3.0 to 3.0 although almost no values are present in the upper deviation, but within a normally distributed bell curve the three deviations contain 99.7 percent of all values. Although this scale is in standard deviation is better to think of it as better or worst overall soil productivity, thus by following zero up from the standard deviation until 50 percent gives a snapshot of how the values lay.

As can be seen in Figure 6, the Cumulative Percentage graph for the Middle Fox River Passageway Region, roughly 22 percent of all Oneota sites are located on soils of average or less than average corn yields, compared to 22 percent of the Unknown sites, with Oneota Village and other both around 30 percent, and even 35 percent of the 165 randomly generated and correlated sites. However, a different pattern is seen among the La Crosse Terrace sites as can be seen in Figure 7. There the Late Prehistoric exhibits a similar trend to the Middle Fox River Passageway trend showing only 50 percent of any value below average production, while the Oneota shows little difference from the rest of the unknown prehistoric sites around 50 percent, but the randomly correlated sites show a percentage of 60 percent. All values were statistically

significant with a range of zero percent to .274 random correlations in the Middle Fox River Passageway Region, while the La Crosse Terrace Region had a range of .043 percent and .106 percent with a huge outlier in the value of Unknown versus Random with the change to be .862 percent random, but they were all an acceptable confidence all over 99 percent. Figures 1-10 in Appendix C depict the K-S Test.

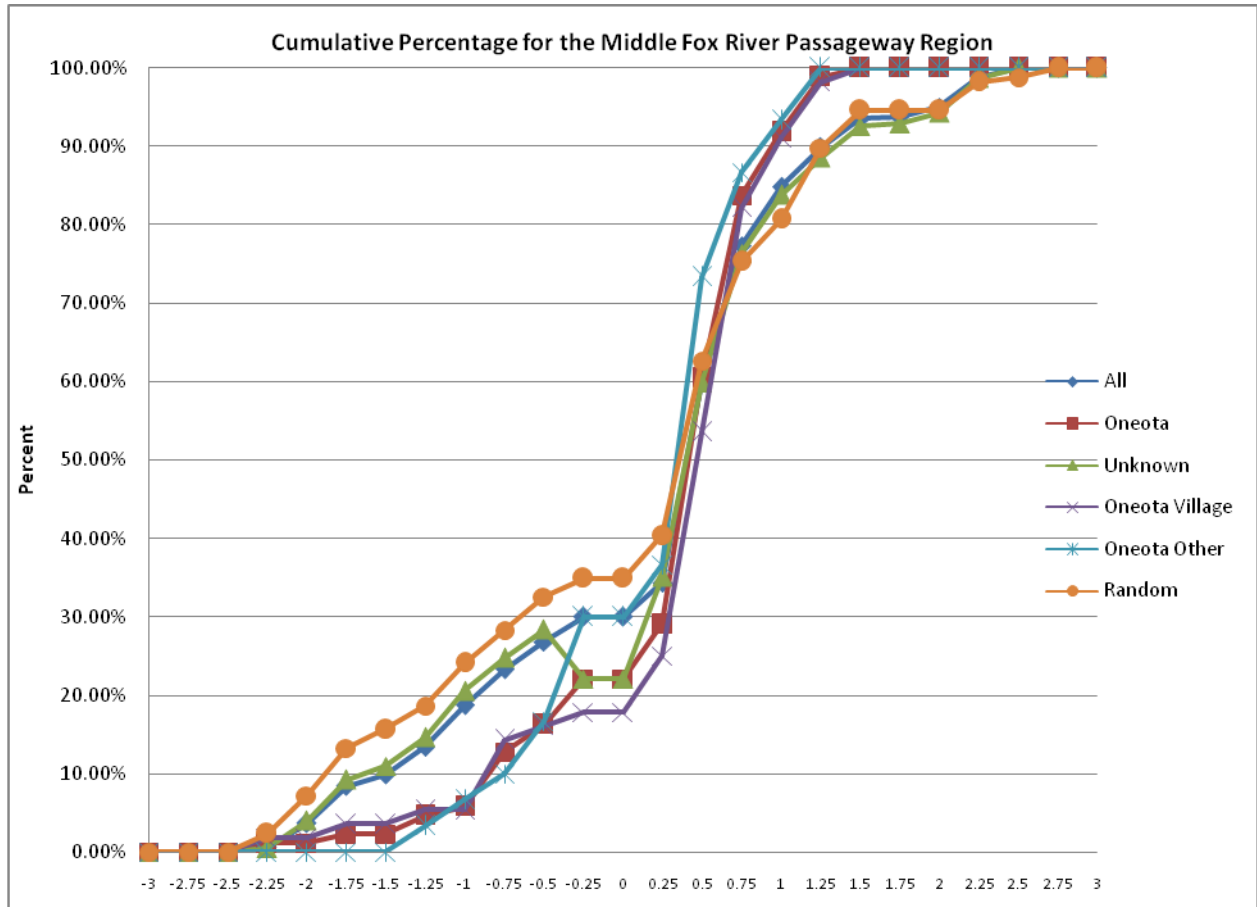

Figure 6: Notice the Oneota low percentage below standard and the upward trend after standardized soils.

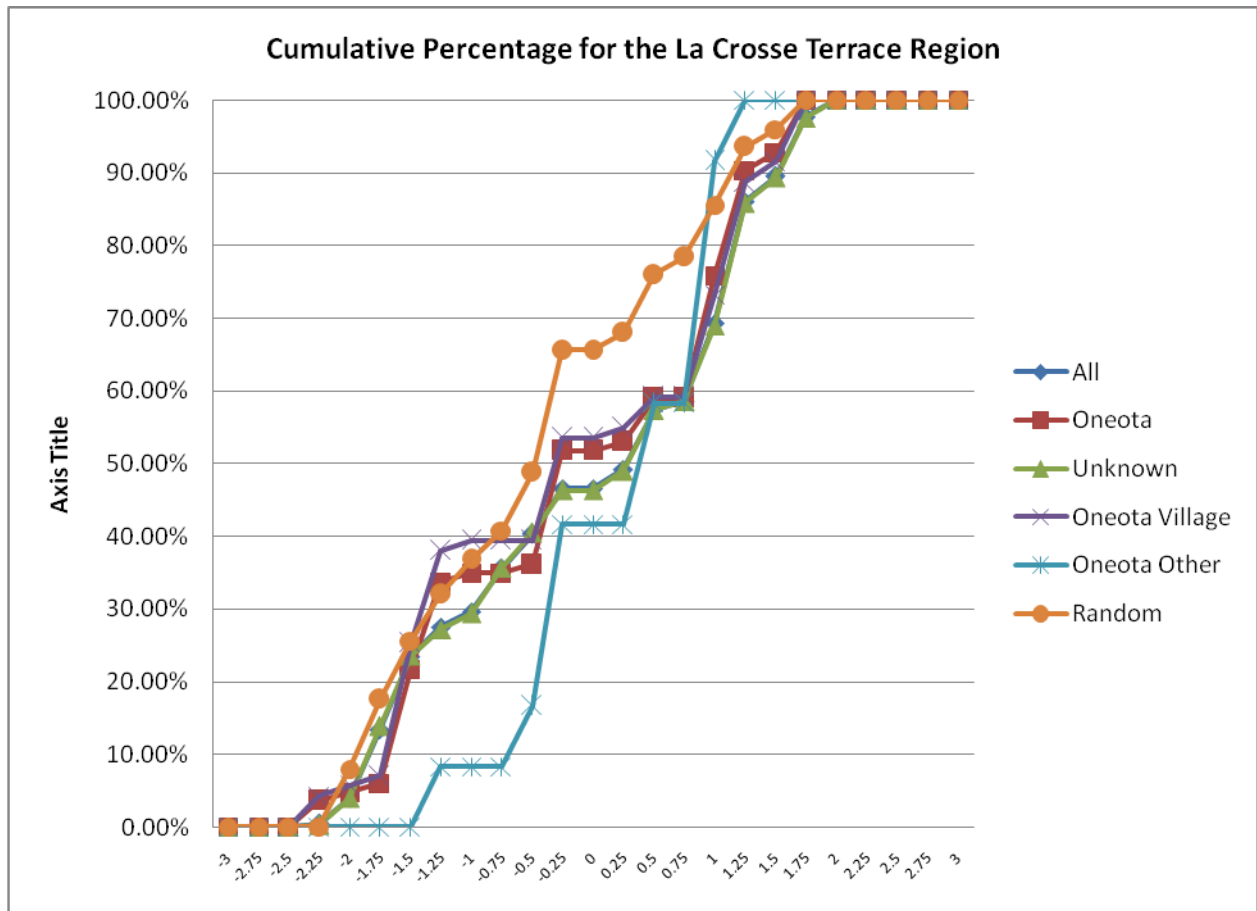

Figure 7: Notice the Late Prehistoric demonstrates a higher agricultural soil trend than the Oneota.

The spectrum is developing placing the La Crosse Terrace Region farthest towards hunting and gathering, the Middle Fox River Passage way as a middle value, and Monongahela remains the most heavily reliant maize agricultural to be run by the agroecological modeling developed by Anderson & Simon (2009b). Even more surprising was that the La Crosse Terrace Region was surpassed by the Ohio Valley Archaic and Woodland, which probably only suggests that Wisconsin's Archaic and Woodland cultures are have even lower productivity but they must also be added before the spectrum can be used effectively (Figure8).

Upland Locales

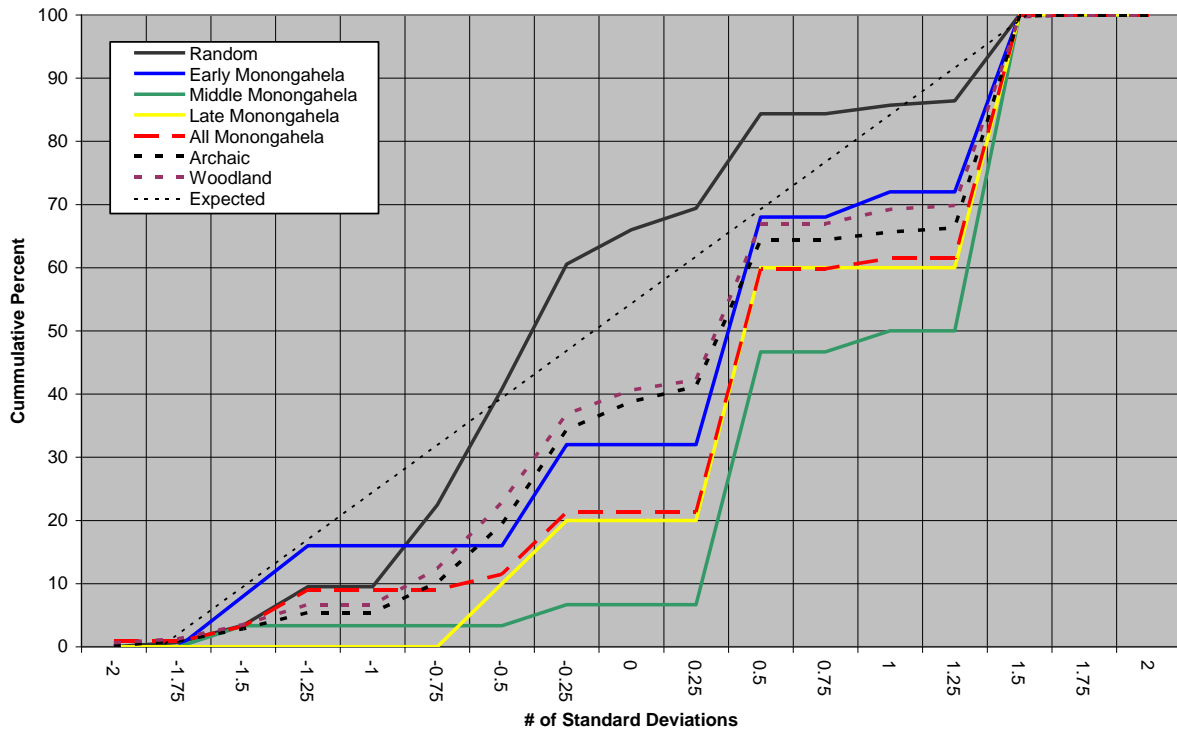

Figure 8: Middle Monongahela reflects a highly positive association with high yield soils.

I was rather surprised to see such a difference in the correlations with agricultural soils between the Oneota localities. One possible reason for the discrepancy is the difference in the level of complexity exhibited during the later time periods. Overstreet (1994) states that the Middle Fox River Passageway had a period of cohesion where hamlets were pulled back into the urban areas. However, the La Crosse Terrace had no such unifying event and were thought to have moved westward towards the Great Plains previous to contact. Perhaps, Wisconsin's poor agricultural soils and fewer frost-free days might have lead Oneota maize horticulturalist to developed more advanced field practices such as the ridged field systems to maintain yields comparable to simply seeking out higher productivity soils like the Monongahela.

The most interesting conclusion is that according to the agroecological patterns of the La Crosse Terrace compared to those of the Middle Fox River Passageway supports a dichotomy between La Crosse Terrace and presumably all the other Oneota localities in Wisconsin. Furthermore, this isn't a closed case because the Lake Koshkonong Region has also reported a heavy reliance on wetland resources especially wild rice resembling the La Crosse Terrace subsistence pattern. Further modeling of the Lake Koshkonong and Door Peninsula Regions would clarify results seen in this study.

FURTHER INVESTIGATION

Possibilities for further investigation are near limitless, but I would suggest three main avenues of study. First, the development of a secure, online database where archaeologist from around the world can upload site information that can be transferred into a searchable database catalog, spatial recorded, and easily converted for GIS usage. This will eliminate the need for every archaeologist to be an ArcGIS expert, while still reaping the benefits of multifaceted spatial analyzation. Also to encourage the development datasets and computer technology directly relevant to the study of archaeology rather other environmental sciences. The thousands of environmental reconstructions carried out could easily be converted for ArcGIS usage especially true for vegetation cover. Hydrology also presents a unique challenge as many prehistoric water sources were from unmarked spring that have dried up from drilling wells today or from a stream that has shifted its path a hundred time since it was use, yet with the aid of geoarchaeologists water sources could be found and mapped for future reference. Secondly, the methodology has to evolve to evaluate soils within traveling distance from a site; it is not very reasonable to assume prehistoric cultures were farming in the center of their settlements. Other ecological

patterns to explore include a sites proximity to multiple resources especially to supplement protein from aquatic, terrestrial, and wetland resources. Methods of reconstructing archaeological ecologies by reconciling environmental reconstructions have provide interesting on a small scale. Richard Edward's 2010 paper on the immediate ecotone surroundings of three Lake Koshkonong settlement found that they were always near an aquatic environment, had vast ecotone diversity, and a large portion of arable land available. Finally, a continuation of agroecological soil assessment throughout the United States and beyond, the Southwest maize agriculture societies would be the next area to explore to possibly surpass the agricultural intensity of the Middle Monongahela.

APPENDIX A

BONE ISTOPE ANALYSIS

Table 1: Bone Isotope analysis values for the Monongahela. (Source: Greenlee 2002)

		SD Vaues
Most Extreme Differences	Absolute	.192
	Positive	.192
	Negative	-.060
Kolmogorov-Smirnov Z		1.295
Asymp. Sig. (2-tailed)		.070

Figure 5: K-S Test between Oneota villages and Random of the La Crosse Terrace Region.

Test Statistics^a

		SD VALUE
Most Extreme Differences	Absolute	.183
	Positive	.183
	Negative	-.111
Kolmogorov-Smirnov Z		1.376
Asymp. Sig. (2-tailed)		.045

Figure 6: K-S Test between Random and Oneota of the Middle Fox River Passageway Region.

Test Statistics^a

		SD VALUE
Most Extreme Differences	Absolute	.148
	Positive	.148
	Negative	-.108
Kolmogorov-Smirnov Z		1.279
Asymp. Sig. (2-tailed)		.076

a. Grouping Variable: K-S Test

Figure 7: K-S Test between Oneota and Unknown Prehistoric of the Middle Fox River Passageway Region.

Test Statistics ^a		SD VALUE
Most Extreme Differences	Absolute	.198
	Positive	.043
	Negative	-.198
Kolmogorov-Smirnov Z		.873
Asymp. Sig. (2-tailed)		.430

Figure 8: K-S Test between Oneota village and other of the Middle Fox River Passageway Region.

Test Statistics ^a		SD Value
Most Extreme Differences	Absolute	.053
	Positive	.031
	Negative	-.053
Kolmogorov-Smirnov Z		.602
Asymp. Sig. (2-tailed)		.862

Figure 9: K-S Test between Unknown Prehistoric and Random of the Middle Fox River Passageway Region.

Test Statistics ^a		SD VALUE
Most Extreme Differences	Absolute	.187
	Positive	.187
	Negative	-.103
Kolmogorov-Smirnov Z		1.213
Asymp. Sig. (2-tailed)		.106

Figure 10: K-S Test between Oneota villages and Random of the Middle Fox River Passageway Region.
